Microbiology and Immunology

Clinical microbiologists are engaged in the field of diagnostic microbiology to determine whether pathogenic microorganisms are present in clinical

specimens collected from patients with suspected infections. If microorganisms are found, these are identified and susceptibility profiles, when indicated, are determined.

During the past two decades, technical advances in the field of diagnostic microbiology have made constant and enormous progress in various areas, including bacteriology,

have improved rapidly and**

have expanded greatly due to a technological revolution in molecular aspects of microbiology and immunology. In particular, rapid techniques for nucleic acid amplification and

characterization combined with automation and user-friendly software have significantly broadened the diagnostic arsenal for the clinical microbiologist. The conventional diagnostic

model for clinical microbiology has been labor-intensive and frequently required days to weeks before test results were available. Moreover, due to the complexity and length

of such testing, this service was usually directed at the hospitalized patient population. The physical structure of laboratories, staffing patterns, workflow, and turnaround time all

**The contemporary crisis of
emerging disease has been a
century and a half in the making.
Human, veterinary, and crop
health practitioners convinced**

themselves that disease could be controlled by medicating the sick, vaccinating those at risk, and eradicating the parts of the biosphere responsible for disease transmission.

Evolutionary biologists assured

themselves that coevolution between pathogens and hosts provided a firewall against disease emergence in new hosts. Most climate scientists made no connection between climate changes and disease. None of

these traditional perspectives anticipated the onslaught of emerging infectious diseases confronting humanity today. As this book reveals, a new understanding of the evolution of pathogen-host systems, called

**the Stockholm Paradigm,
explains what is happening. The
planet is a minefield of
pathogens with preexisting
capacities to infect susceptible
but unexposed hosts, needing
only the opportunity for contact.**

Climate change has always been the major catalyst for such new opportunities, because it disrupts local ecosystem structure and allows pathogens and hosts to move. Once pathogens expand to new hosts,

novel variants may emerge, each with new infection capacities. Mathematical models and real-world examples uniformly support these ideas. Emerging disease is thus one of the greatest climate change–related

**threats confronting humanity.
Even without deadly global
catastrophes on the scale of the
1918 Spanish Influenza
pandemic, emerging diseases
cost humanity more than a
trillion dollars per year in**

treatment and lost productivity. But while time is short, the danger is great, and we are largely unprepared, the Stockholm Paradigm offers hope for managing the crisis. By using the DAMA (document, assess,

**monitor, act) protocol, we can
“anticipate to mitigate” emerging
disease, buying time and saving
money while we search for more
effective ways to cope with this
challenge.**
